BINARY SEARCH TREE

QUESTION:-

Create a Node structure with data, left, and right pointers.

Implement functions for:

Insertion: Recursively add nodes while maintaining the BST property (left subtree < node < right subtree).

Deletion: Handle different cases (leaf node, single child, two children).

Search: Recursively search for a specific value, returning the node or NULL if not found.

In-order Traversal: Print nodes in ascending order (left subtree, node, right subtree).

2. Pre-order and Post-order Traversal of a Binary Tree:

Modify the in-order traversal function from question 1 to perform pre-order (root, left, right) and post-order (left, right, root) traversals.

Check if a Binary Tree is a Binary Search Tree (BST):

Implement a recursive function that checks if the left subtree is less than the current node and the right subtree is greater than the current node.

Traverse the tree and return false if any violation is found, otherwise return true.

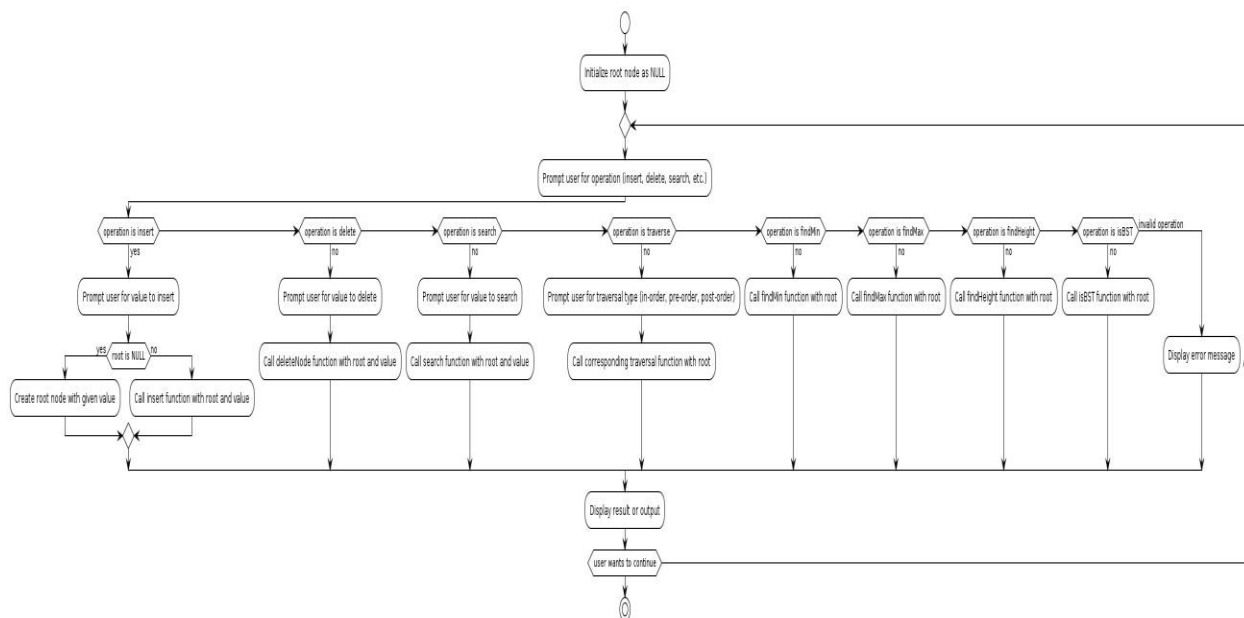

Find the Height of a Binary Tree:

Implement a recursive function that returns the maximum depth (height) from the root to a leaf node.

Find the Minimum and Maximum Values in a Binary Tree:

Modify the in-order traversal function to track the minimum and maximum values encountered so far.

FLOWCHART

MODULAR CODE

Bst.h:-

```
#ifndef BSTFUNC_H
```

```
#define BSTFUNC_H
```

```
// Structure for a Node in BST
```

```
struct TreeNode {  
    int data;  
    struct TreeNode* left;  
    struct TreeNode* right;  
};
```

```
typedef struct TreeNode TreeNode;
```

```
// Function declarations
```

```
TreeNode* createNode(int data);  
TreeNode* insert(TreeNode* root, int data);  
TreeNode* deleteNode(TreeNode* root, int  
key);

CLOCKS_PER_SEC;
printf("Time taken: %f seconds\n",
cpu_time_used);

return 0;
}
```

EXPLANATION

Node Structure:

A node in a BST contains three parts: data, left pointer, and right pointer.

The data represents the value stored in the node.

The left pointer points to the left child node.

The right pointer points to the right child node.

Insertion:

To insert a value into a BST, start from the root node.

If the tree is empty, create a new node as the root with the given value.

Otherwise, recursively traverse the tree:

If the value is less than the current node's data, move to the left subtree.

If the value is greater than the current node's data, move to the right subtree.

Repeat until an appropriate empty spot is found, then insert the new node.

Deletion:

Deleting a node from a BST requires handling different cases:

If the node to delete is a leaf node, simply remove it.

If the node has only one child, bypass it by connecting its parent directly to its child.

If the node has two children, find its successor (the minimum value in its right subtree), replace the node's data with the successor's data, and recursively delete the successor node.

Search:

Searching for a value in a BST involves recursively traversing the tree:

If the current node is NULL or contains the value, return the node.

If the value is less than the current node's data, search the left subtree.

If the value is greater than the current node's data, search the right subtree.

In-order Traversal:

In-order traversal prints the nodes of the BST in ascending order:

Traverse the left subtree recursively.

Visit the current node.

Traverse the right subtree recursively.

Pre-order and Post-order Traversal of a Binary Tree:

Pre-order traversal starts from the root, then visits the left subtree, and finally visits the right subtree.

Post-order traversal starts from the left subtree, then visits the right subtree, and finally visits the root.

Check if a Binary Tree is a Binary Search Tree (BST):

The function recursively checks if the left subtree is less than the current node and the right subtree is greater than the current node. It traverses the tree and returns false if any violation is found, otherwise returns true.

Find the Height of a Binary Tree:

The function returns the maximum depth (height) from the root to a leaf node. It recursively calculates the height of the left and right subtrees, then returns the maximum height plus one.

Find the Minimum and Maximum Values in a Binary Tree:

Modify the in-order traversal function to track the minimum and maximum values encountered so far.

At each node, update the minimum and maximum values if necessary.

rps@rps-virtual-machine: ~/day17

rps@rps-virtual-machine:~/day17$ For the function's children, the fields have the following meanings:

self      This is the amount of time that was propagated directly
          from the child into the function.

children  This is the amount of time that was propagated from the
          child's children to the function.

called    This is the number of times the function called
          this child. '/' the total number of times the child
          was called. Recursive calls by the child are not
          listed in the number after the '/'.

name      This is the name of the child. The child's index
          number is printed after it. If the child is a
          member of a cycle, the cycle number is printed
          between the name and the index number.

If there are any cycles (circles) in the call graph, there is an
entry for the cycle-as-a-whole. This entry shows who called the
cycle (as parents) and the members of the cycle (as children.)
The '+' recursive calls entry shows the number of function calls that
were internal to the cycle, and the calls entry for each member shows,
for that member, how many times it was called from other members of
the cycle.
